## ABSTRACT

In this work we present constraints on different shapes of primordial non-Gaussianity using the Wilkinson Microwave Anisotropy Probe (WMAP) 7-year data and the spherical Mexican hat wavelet  $f_{nl}$  estimator including the linear term correction. In particular we focus on the local, equilateral and orthogonal shapes. We first analyse the main statistical properties of the wavelet estimator and show the conditions to reach optimality. We include the linear term correction in our estimators and compare the estimates with the values already published using only the cubic term. The estimators are tested with realistic WMAP simulations with anisotropic noise and the WMAP  $KQ75$  sky cut. The inclusion of the linear term correction shows a negligible improvement ( $\leq 1$  per cent) in the error bar for any of the shapes considered. The results of this analysis show that, in the particular case of the wavelet estimator, the optimality for WMAP anisotropy levels is basically achieved with the mean subtraction and in practical terms there is no need of including a linear term once the mean has been subtracted. Our best estimates are now:  $\hat{f}_{nl}^{(loc)} = 39.0 \pm 21.4$ ,  $\hat{f}_{nl}^{(eq)} = -62.8 \pm 154.0$  and  $\hat{f}_{nl}^{(ort)} = -159.8 \pm 115.1$ . We have also computed the expected linear term correction for simulated Planck maps with anisotropic noise at 143 GHz following the Planck Sky Model and including a mask. The improvement achieved in this case for the local  $f_{nl}$  error bar is also negligible (0.4 per cent).

**Key words:** methods: data analysis - cosmic microwave background

## 1 INTRODUCTION

In the recent years the spherical Mexican hat wavelet (SMHW) (Martínez-González et al. 2002) has been used to construct a new type of estimator for the primordial non-Gaussianity in the CMB characterised by the non-linear coupling parameter  $f_{nl}$  (Curto et al. 2009a,b, 2010, 2011a,b). One of the particularities of the wavelet estimator as it has been traditionally presented in the literature compared with direct bispectrum-based estimators (Komatsu & Spergel 2001; Komatsu et al. 2002, 2003; Babich et al. 2004; Babich 2005; Creminelli et al. 2006, 2007; Yadav & Wandelt 2008; Smith et al. 2009; Elsner & Wandelt 2009; Liguori et al. 2010; Senatore et al. 2010; Smidt et al. 2010; Fergusson et al. 2010a,b; Komatsu et al. 2011; Fergusson & Shellard 2011) is the absence of a linear term. In the bispectrum-based estimators, the linear term plays a key role to achieve optimality in the cases where the rotational invariance of the CMB

is broken because of different instrumental complexities such as anisotropic noise or partial sky coverage (see for example Creminelli et al. 2006, 2007; Yadav & Wandelt 2010; Fergusson & Shellard 2011).

The computational difficulties related to the inversion of the covariance matrix present in the bispectrum estimator, especially in future data sets with higher  $\ell_{max}$  as for example Planck<sup>1</sup>, together with the unknown effect that different systematics from the instrument and background residuals might have on the estimates, motivated the search for new estimators based on different tools such as the SMHW described in this paper, the binned bispectrum (Bucher et al. 2010), the general modal expansion and polyspectra estimation (Fergusson et al. 2010b; Fergusson & Shellard 2011), the needlets (Marinucci et al. 2008; Pietrobon et al. 2009; Rudjord et al. 2009; Donzelli et al. 2012), the HEALPix wavelet (Casaponsa et al. 2011a), neural networks (Casaponsa et al. 2011b) or a Bayesian approach (Elsner et al. 2010; Elsner & Wandelt 2010) among others.

<sup>1</sup> <http://www.esa.int/planck>

In a previous paper (Curto et al. 2011a), we described the main features of the wavelet estimator based on the cubic statistics constructed from the SMHW coefficient maps. Those cubic terms were written as a function of the non-linear coupling parameter  $f_{nl}$  and the bispectrum of the primordial non-Gaussianity. In that paper we also showed that the power of the method to detect  $f_{nl}$ , that is the variance of this parameter  $\sigma^2(f_{nl})$ , matches that of the direct bispectrum-based estimators for ideal conditions (full sky and isotropic noise) and realistic conditions (partial sky coverage and anisotropic noise). The wavelet estimator variance was obtained in two different ways: through the Fisher matrix and by means of Monte Carlo (MC) simulations, providing very similar results. A remarkable result of these works is the fact that the wavelet estimator is, in practice, able to reach optimality on the  $f_{nl}$  estimation without including any linear term correction. However, from several works (see for example Creminelli et al. 2006; Fergusson & Shellard 2011) it has been shown that in order to reach minimum variance, all the cubic estimators need a linear term correction. A recent work has solved this apparent controversy (Donzelli et al. 2012) by showing that in WMAP<sup>2</sup> anisotropy conditions, the linear term correction is nearly equivalent to the mean subtraction performed for each wavelet coefficient map in the wavelet estimator.

In this paper we re-examine the main statistical properties of the wavelet estimator and show the conditions to reach optimality. We compute the linear term correction for the local, equilateral and orthogonal  $f_{nl}$  shapes. In particular we see that the linear term correction for the local case provides a 1 per cent reduction in the error bars (in agreement with Donzelli et al. 2012, for the SMHW) while the correction for the other shapes is even smaller. Section 2 introduces the SMHW estimator, its variance and its linear correction. In Section 3 the estimator with its linear correction is applied to WMAP 7-year data for the local, equilateral and orthogonal shape. In Section 4 we explore the linear correction on Planck simulations at 143 GHz for the local shape, and in Section 5 the conclusions are presented.

## 2 THE WAVELET APPROACH

In this Section we present an approach for the  $f_{nl}$  estimator based on the statistical properties of the cubic terms of the SMHW coefficients averaged over the sky. In this case we exploit the property of the SMHW wavelet that performs a strong decorrelation of the data at distances larger than the wavelet resolution. The expected value of the cubic terms in the sky are obtained from the sum of a large number of almost independent elements and therefore its distribution will be close to Gaussian by the central limit theorem. We will first review the SMHW and its decorrelation properties and then we will construct the wavelet estimator based on those properties including the linear term correction.

**Figure 1.** The normalised correlation functions for different wavelet coefficient maps are plotted. From left to right, the curves correspond to maps convolved with a SMHW of scale  $R = 0.27$ ,  $0.64$ ,  $1.50$ ,  $3.54$  and  $8.33$  degrees, respectively.

### 2.1 The SMHW coefficients and their correlation

Detailed information about the spherical Mexican Hat wavelet (SMHW) and a (non-complete) list of applications to the CMB maps and cosmology can be found in Antoine & Vanderghenst (1998); Martínez-González et al. (2002); Cayón et al. (2003); Vielva et al. (2006); Vielva (2007); McEwen et al. (2007); Martínez-González (2008); Zhang et al. (2011); Yu et al. (2012).

Given a function  $f(\mathbf{n})$  defined at a position  $\mathbf{n}$  on the sphere and a continuous wavelet family on that space  $\Psi(\mathbf{n}; \mathbf{b}, R)$ , we define the continuous wavelet transform as

$$w(R; \mathbf{b}) = \int d\mathbf{n} f(\mathbf{n}) \Psi(\mathbf{n}; \mathbf{b}, R) \quad (1)$$

where  $\mathbf{b}$  is the position on the sky at which the wavelet coefficient is evaluated,  $R$  is the scale of the wavelet and  $\Psi_S(\theta; R) \equiv \Psi(\mathbf{n}(\theta, \phi); \mathbf{0}, R)$  is given by

$$\Psi_S(\theta; R) = \frac{1}{\sqrt{2\pi}N(R)} \left[ 1 + \left( \frac{y}{2} \right)^2 \right]^2 \left[ 2 - \left( \frac{y}{R} \right)^2 \right] e^{-y^2/(2R^2)} \quad (2)$$

where

$$N(R) = R \left( 1 + \frac{R^2}{2} + \frac{R^4}{4} \right)^{1/2} \quad (3)$$

and

$$y = 2 \tan \left( \frac{\theta}{2} \right). \quad (4)$$

Considering a set of different angular scales  $\{R_i\}$  we define a third order statistic depending on three scales  $\{i, j, k\}$  (Curto et al. 2009b)

$$q_{ijk} = \frac{1}{4\pi} \frac{1}{\sigma_i \sigma_j \sigma_k} \int d\mathbf{n} w(R_i, \mathbf{n}) w(R_j, \mathbf{n}) w(R_k, \mathbf{n}) \quad (5)$$

where  $\sigma_i$  is the dispersion of the wavelet coefficient map  $w(R_i, \mathbf{n})$ . In the particular case of  $R_0 = 0$ ,  $w(R_0, \mathbf{n}) \equiv f(\mathbf{n})$ . For a particular pixelization on the sphere, Eq. 5 can be written as:

<sup>2</sup> <http://map.gsfc.nasa.gov/>

$$\mathbf{q}_{ijk} = \frac{1}{N_{ijk}} \sum_{\mathbf{p}=0}^{N_{pix}-1} \frac{\mathbf{w}_i(\mathbf{p})\mathbf{w}_j(\mathbf{p})\mathbf{w}_k(\mathbf{p})}{\sigma_i\sigma_j\sigma_k} \quad (6)$$

where  $N_{pix}$  is the total number of pixels of the map,  $N_{ijk}$  is the number of pixels available after combining the extended masks corresponding to the three scales  $R_i$ ,  $R_j$  and  $R_k$  and  $w_i(p) \equiv w(R_i, p) - \langle w(R_i) \rangle$  is the wavelet coefficient in the pixel  $p$  evaluated at the scale  $R_i$  after subtracting the mean value over the wavelet coefficient map outside its extended mask.

Using the properties of the wavelet, we may write the wavelet transform of the temperature map in the next form (Curto et al. 2011a)

$$w(R_i, \mathbf{n}) = \sum_{\ell m} a_{\ell m} \omega_{\ell}(R_i) Y_{\ell m}(\mathbf{n}). \quad (7)$$

Using the isotropic properties of the CMB and the properties of the wavelet, we can obtain the angular coefficient correlation  $C_{ij}(\theta)$  between any pair of pixels  $\mathbf{n}$  and  $\mathbf{n}'$  separated by an angular distance  $\mathbf{nn}' = \cos(\theta)$  and for two angular scales  $R_i$  and  $R_j$

$$\begin{aligned} C_{ij}(\theta) &\equiv \langle w(R_i, \mathbf{n}) w(R_j, \mathbf{n}') \rangle = \\ &= \sum_{\ell} \frac{2\ell+1}{4\pi} C_{\ell} \omega_{\ell}(R_i) \omega_{\ell}(R_j) P_{\ell}(\cos(\theta)) \end{aligned} \quad (8)$$

where  $\omega_{\ell}(R)$  is the window function of the wavelet at a scale  $R$  and it is given by the harmonic transform of the mother wavelet of the SMHW (Martínez-González et al. 2002; Sanz et al. 2006). The dispersion of the wavelet coefficients at scale  $R_i$  is simply given by  $\sigma_i = C_{ii}(\theta = 0)^{1/2}$ .

In Fig. 1 we show the correlation of the wavelet coefficients as a function of the angular distance  $\theta$  for several values of the resolution scale  $R$ . As can be seen, the SMHW produce an effective decorrelation of the signal at angular distances above the resolution scale  $R$ .

## 2.2 The wavelet estimator

Considering the strong decorrelation produced by the convolution of the SMHW on the temperature anisotropies, we can now apply the central limit theorem to the cubic statistics defined in Eq. (5). Since the average value is calculated from the sum of a very large number of almost independent elements (of the order of the number of pixels in the sphere with size that of the resolution scale  $R$ ), then its distribution should be very close to a Gaussian. This is actually seen in Fig. 2, where the distribution of the cubic terms for different SMHW scales are shown. These distributions have been obtained from MC simulations of Gaussian temperature anisotropies.

The previous results indicate that, for Gaussian temperature anisotropies, a good representation of the  $n$ -point distribution of the quantities  $q_{ijk}$  can be given in terms of a multinormal distribution. Allowing now for the presence of weak non-Gaussianity for the temperature anisotropies (e.g. an amplitude for the primordial non-Gaussianity consistent with WMAP data) one can use the next likelihood for the  $f_{nl}$  parameter:

$$L(f_{nl}) \propto e^{-\chi^2(f_{nl})/2}, \quad (9)$$

where  $\chi^2(f_{nl})$  is given by

$$\chi^2(f_{nl}) = \sum_{ijk, rst} (q_{ijk}^{obs} - f_{nl} \alpha_{ijk}) C_{ijk, rst}^{-1} (q_{rst}^{obs} - f_{nl} \alpha_{rst}), \quad (10)$$

where  $q_{ijk}^{obs}$  are the cubic statistics corresponding to the observed data,  $\alpha_{ijk} = \langle q_{ijk} \rangle_{f_{nl}=1}$  and  $C_{ijk, rst}$  is the covariance matrix of the cubic statistics. A further test to check that the  $q_{ijk}$  are normally distributed can be done by considering the property that  $\Delta\chi^2(f_{nl}) = \chi^2(f_{nl}) - \chi_{min}^2(f_{nl})$  is a  $\chi^2$  distribution with one degree of freedom. In particular,  $\Delta\chi^2(f_{nl}) = 1(4)$  should provide the 1(2)-sigma or 68 per cent(95 per cent) confidence intervals for the  $f_{nl}$  parameter. Using MC simulations we have checked that this is the case for the  $q_{ijk}$  statistics.

After straightforward calculation, it can be easily seen that the  $f_{nl}$  estimator in this case is given by

$$\hat{f}_{nl} = \frac{\sum \alpha_{ijk} C_{ijk, rst}^{-1} q_{rst}}{\sum \alpha_{ijk} C_{ijk, rst}^{-1} \alpha_{rst}} \quad (11)$$

while that the variance of the  $\hat{f}_{nl}$  parameter in Eq. (11) is given by

$$\begin{aligned} \sigma_F^2(\hat{f}_{nl}) &= \frac{-1}{\left\{ \frac{\partial^2 \log L(f_{nl})}{\partial f_{nl}^2} \right\}_{f_{nl}=\hat{f}_{nl}}} = \\ &= \frac{1}{\frac{1}{2} \left\{ \frac{\partial^2 \chi^2(f_{nl})}{\partial f_{nl}^2} \right\}_{f_{nl}=\hat{f}_{nl}}} = \frac{1}{\sum_{ijk, rst} \alpha_{ijk} C_{ijk, rst}^{-1} \alpha_{rst}}. \end{aligned} \quad (12)$$

This estimator has already been shown to be nearly optimal on WMAP data (Curto et al. 2009a,b, 2010, 2011a,b) without the need of subtracting any linear term. However, as stated in Donzelli et al. (2012), from all the possible cubic combinations of three Gaussian variables, the Wick polynomials are shown to have minimum variance. This implies that in order to have a strictly speaking minimum variance estimator, a linear term correction needs to be included. In fact the linear term subtraction is equivalent to the mean subtraction at each wavelet coefficient map (Donzelli et al. 2012) for low levels of anisotropy. This is indeed the procedure that has been followed in Curto et al. (2009a,b, 2010, 2011a,b) and it explains the competitive results obtained just by subtracting the mean using the estimator in Eq. 11.

The linear term correction for the wavelet estimator can be written as:

$$\hat{f}_{nl}^{(total)} = \hat{f}_{nl}^{(cubic)} - \hat{f}_{nl}^{(linear)}, \quad (13)$$

where  $\hat{f}_{nl}^{(cubic)}$  is given by Eq. 11 and

$$\hat{f}_{nl}^{(linear)} = \sigma_F^2(\hat{f}_{nl}) \sum_{ijk, rst} \alpha_{ijk} C_{ijk, rst}^{-1} q_{rst}^{(L)} \quad (14)$$

with

$$\begin{aligned} q_{ijk}^{(L)} &= \frac{1}{N_{ijk}} \sum_p \left\{ \left\langle \frac{w_i(p)}{\sigma_i} \frac{w_j(p)}{\sigma_j} \right\rangle \frac{w_k(p)}{\sigma_k} + \right. \\ &\left. \left\langle \frac{w_i(p)}{\sigma_i} \frac{w_k(p)}{\sigma_k} \right\rangle \frac{w_j(p)}{\sigma_j} + \left\langle \frac{w_j(p)}{\sigma_j} \frac{w_k(p)}{\sigma_k} \right\rangle \frac{w_i(p)}{\sigma_i} \right\}. \end{aligned} \quad (15)$$

In the next Sections we apply the wavelet estimator to WMAP 7-year data as well as to Planck simulations and compare the results obtained with and without the linear term correction.

**Figure 2.** Histograms of the cubic statistics  $q_{iii}$  for the different angular scales  $R_i$  considered in previous works (Curto et al. 2011a,b).

### 3 APPLICATION TO WMAP V+W DATA

We have computed the linear term correction to the cubic wavelet  $f_{nl}$  estimator for the three shapes with a relevant interest in many inflationary models: the local, equilateral and orthogonal shapes (see for example Bartolo et al. 2004; Senatore et al. 2010; Komatsu et al. 2011). The estimator can be easily applied to other bispectra with a separable shape (Curto et al. 2011a). Results taking into account only the cubic contribution are already published (Curto et al. 2011b).

We have selected the same set of 15 angular scales from  $R_0 = 0$  arcmin to  $R_{14} = 767.3$  arcmin used in Curto et al. (2011b). We have considered the V+W WMAP data optimally weighted by the  $N_{hits}$  maps per radiometer in order to maximise the signal-to-noise ratio. We also consider the same WMAP  $KQ75$  mask and its extended masks for each wavelet angular scale. The cubic covariance matrix has been computed using 10000 Gaussian simulations. A principal component analysis has been performed in order to avoid contamination from the lowest noisy eigenvalues of this covariance matrix without losing non-Gaussian signal (Curto et al. 2011a). The two point correlation matrices needed for the linear term correction have also been estimated with 64000 Gaussian simulations. This number of simulations is needed in order to achieve the required precision in the estimation of the correlation matrices.

We have applied the estimator to one set of 10000 Gaussian maps and the WMAP data. The results are presented in Fig. 3 for the three considered shapes. In the left panels, the red histograms correspond to the best-fitting  $f_{nl}$  values obtained with the cubic estimator and the black histograms correspond to the best-fitting  $f_{nl}$  values after the linear term correction. The vertical lines correspond to the actual WMAP data values estimated with the cubic estimator (red) and the linearly corrected estimator (black). In the right panels, we compare the best-fitting  $f_{nl}$  values for the same set of Gaussian simulations. Note that both  $f_{nl}^{(cubic)}$  and  $f_{nl}^{(total)}$  are highly correlated and the deviations are not significant. Finally in Tables 1, 2 and 3 the previous results are summarised. We present the WMAP 7-year  $f_{nl}$  best-fitting values for the cubic estimator  $f_{nl}^{(cubic)}$ , the linear estimator  $f_{nl}^{(linear)}$ , and  $f_{nl}^{(total)}$  for the clean and raw (uncleaned) maps. The Fisher  $f_{nl}$  error bar as described in Eq. 25 of Curto et al. (2011a) is also provided. For each case, we observe a small reduction of the error bars when the linear term is included. The largest correction is introduced in the local shape, where  $\sigma$  is reduced from  $\sigma(f_{nl}) = 21.6$  to  $\sigma(f_{nl}) = 21.4$  (i.e. a reduction of 1 per cent, in agreement with Donzelli et al. 2012). The correction for the other two cases, equilateral and orthogonal is also negligible (about 0.2 per cent and 0.1 per cent respectively). This is in agreement with Creminelli et al. (2006) for the equilateral shape, where the standard deviations of  $f_{nl}$  without the linear term

**Figure 3.** WMAP 7-year data best-fitting  $f_{nl}$  values using the cubic estimator (Eq. 11) and the estimator with the linear correction (Eq. 13) for the local (*top*), equilateral (*middle*) and orthogonal (*bottom*) shapes. In the left panels the histogram of the best-fitting  $f_{nl}$  values with (dashed dark line) and without (solid red line) the linear term correction for each simulation are plotted. Vertical lines correspond to the values obtained with WMAP data. The right pannels show the corresponding correlation between the same estimates.

were found closer to the lower Fisher limit than in the local shape, suggesting a less important contribution of the linear term correction.

Our best-fitting values, computing  $\sigma(f_{nl})$  with 10000 Gaussian simulations to characterize the errors, are presented below for the three shapes.

#### Local form results<sup>3</sup>:

- $f_{nl}^{(cubic)} = 38.9 \pm 21.6$

<sup>3</sup> The average  $\langle q_{ijk} \rangle_{f_{nl}}$  is obtained using 1000 non-Gaussian simulations of the local shape generated by the procedure described in (Elsner & Wandelt 2009) and publicly available at <http://planck.mpa-garching.mpg.de/cmb/fnl-simulations/>

The best estimates of the local shape presented in Curto et al. (2011b) are  $f_{nl}^{(cubic)} = 32.5 \pm 22.5$ . Note that in that work, a perturbative approach is considered to simulate the non-Gaussian simulations used to compute  $\langle q_{ijk} \rangle_{f_{nl}}$ . The different approaches to simulate the non-Gaussianity and the statistical errors due to the finite number of non-Gaussian simulations explains the small differences between the error bars presented here and in that reference.

- $f_{nl}^{(total)} = 39.0 \pm 21.4$

#### Equilateral form results:

- $f_{nl}^{(cubic)} = -53.3 \pm 154.3$
- $f_{nl}^{(total)} = -62.8 \pm 154.0$

#### Orthogonal form results:

- $f_{nl}^{(cubic)} = -155.1 \pm 115.1$
- $f_{nl}^{(total)} = -159.8 \pm 115.1$

In order to check that the estimator has already reached optimality with the considered scales for the three shapes, we have computed  $\sigma(f_{nl})$  for different subsets of scales (Fig. 4). We compare the  $f_{nl}$  error bars for different minimum angular scales  $R_{min}$ . To find the equivalent multipole  $\ell$  range corresponding to each  $R_{min}$  see Fig. 5 of Curto et al. (2011a). The three shapes reach minimum variance for  $R_{min} = 0$  arcmin.

The error bar of the equilateral and orthogonal shapes are also similar to the values obtained with the direct bispectrum estimator where  $\sigma(f_{nl}) = 140$  for the equilateral shape and  $\sigma(f_{nl}) = 104$  for the orthogonal shape (Komatsu et al.

**Table 1.** Constraints on the  $f_{nl}$  parameter for the local shape with and without the linear term correction. **Figure 4.** The  $f_{nl}$  error bars computed using different  $R_{min}$  angular scales for the local (left), equilateral (middle) and orthogonal (right) shapes. The diamonds corresponds to  $f_{nl}^{cubic}$  and the crosses to  $f_{nl}^{total}$ .

2011). The slightly larger values ( $\sim 9$  per cent) obtained from the dispersion of the  $f_{nl}$  distribution corresponding to 10000 Gaussian simulations,  $\sigma(f_{nl}) = 154$  and  $\sigma(f_{nl}) = 115$  respectively, are likely due to differences in the perturbative approach used to simulate the non-Gaussian signal of these two shapes (Curto et al. 2011b) or the statistical errors due to the finite number of non-Gaussian simulations.

#### 4 APPLICATION TO PLANCK SIMULATIONS

We have computed the linear term correction to the cubic wavelet  $f_{nl}$  estimator for the local shape using Planck simulations in order to forecast the amplitude of this correction on future Planck analyses. We do not consider the two other shapes (equilateral and orthogonal). From the results of pre-

vious sections, we expect the correction for those cases to be even smaller.

For this analysis we have considered a new set of angular scales that better suits the range of angular multipoles which are cosmic variance dominated ( $\ell_{max} \sim 2000$ ). The list of angular scales is  $R_0 = 0$ ,  $R_1 = 1.3$ ,  $R_2 = 2.1$ ,  $R_3 = 3.4$ ,  $R_4 = 5.4$ ,  $R_5 = 8.7$ ,  $R_6 = 13.9$ ,  $R_7 = 22.3$ ,  $R_8 = 35.6$ ,  $R_9 = 57.0$ ,  $R_{10} = 91.2$ ,  $R_{11} = 146.0$ ,  $R_{12} = 233.5$ ,  $R_{13} = 373.6$ ,  $R_{14} = 597.7$  and  $R_{15} = 956.3$  arcmin. As a representative mask, we have used the available WMAP  $KQ75$  mask (75 per cent of the sky). We have simulated the Planck 143 GHz channel using a fiducial CMB power spectrum that best fits WMAP 7-year data,  $\ell_{max} = 2048$  and a Gaussian beam with  $FWHM = 7.1$  arcmin. The noise has been generated using an anisotropic  $N_{hits}$  map computed from the scanning

**Table 4.** Expected constraints on the  $f_{nl}$  parameter for the local shape with and without the linear term correction for the 143 GHz Planck channel. From left to right, the mean, dispersion, 16, 84, 2.5 and 97.5 per cent quantiles respectively of the  $f_{nl}$  distribution obtained with 1000 Gaussian maps. The Fisher error bar obtained for this case is  $\sigma_F(f_{nl}) = 7.5$ .

| case           | $\langle f_{nl} \rangle$ | $\sigma(f_{nl})$ | $X_{16}$ | $X_{84}$ | $X_{2.5}$ | $X_{97.5}$ |
|----------------|--------------------------|------------------|----------|----------|-----------|------------|
| cubic          | 0.4                      | <b>7.98</b>      | -7.2     | 8.6      | -15.0     | 17.2       |
| linear         | 0.0                      | <b>1.43</b>      | -1.4     | 1.5      | -2.7      | 2.8        |
| cubic - linear | 0.4                      | <b>7.95</b>      | -7.4     | 8.2      | -15.4     | 16.7       |

strategy of the Planck Sky Model<sup>4</sup> (Delabrouille et al. 2012) and the noise sensitivity per pixel provided in the Planck Bluebook<sup>5</sup> (using an average noise sensitivity for 14 months of  $\sigma_{noise} = 2.2 \mu\text{K/K}$  in a square pixel whose size is the FWHM extent of the beam).

The cubic covariance matrix and the linear correlation matrices needed for the  $f_{nl}$  estimator in Eq. (13) have been computed using two independent sets of 10000 Planck Gaussian simulations. The results corresponding to the analysis of an additional set of 1000 Gaussian maps are presented in Fig. 5. Note that for this simulated Planck level of anisotropy,  $f_{nl}^{(cubic)}$  and  $f_{nl}^{(total)}$  are also highly correlated. Finally in Table 4 the properties of the previous histograms are summarised. In particular, we see that using the cubic estimator  $\sigma(f_{nl}) = 7.98$  and the linear term contribution reduces this error bar to  $\sigma(f_{nl}) = 7.95$  (i.e. a negligible correction lower than 0.4 per cent).

## 5 CONCLUSIONS

In this paper we have performed a comprehensive study of the  $f_{nl}$  wavelet estimator. We have considered the main statistical assumptions to derive the estimator in terms of the cubic quantities  $q_i$  and showed the conditions to reach optimality. We have found that the SMHW wavelet produces an important effective decorrelation of the signal at angular distances above the angular resolution  $R$ . This means that the cubic quantities are nearly Gaussian owing to the central limit theorem and using this property we have found an expression for the likelihood of the  $f_{nl}$  parameter in terms of the cubic statistics. We have also included a linear term correction following the Wick polynomials introduced by Donzelli et al. (2012). In particular, we have confirmed that the linear term correction is basically achieved through the mean subtraction that we carry out on the wavelet coefficient maps for each angular scale (Curto et al. 2011a,b). We find that, in this case, the linear term correction only reduces the error bars about 1 per cent for the local case using WMAP data. This correction is even smaller for the equilateral and orthogonal cases (0.2 per cent and 0.1 per cent respectively). The results presented in this paper are in agreement with the optimal results obtained with the wavelet estimator already published where the mean subtraction was performed (Curto et al. 2009a,b, 2010, 2011a,b). Therefore,

we conclude that the contribution of the linear term is negligible ( $\leq 1$  per cent) for the SMHW estimator for the three considered shapes. We have also explored the linear term correction for Planck simulations at the 143 GHz channel. Our results indicate that the correction for the local shape is lower than 0.4 per cent considering the expected levels of noise anisotropy for this channel and the WMAP KQ75 mask. From the results on WMAP data, we expect the correction for the equilateral and orthogonal shapes to be even smaller.

## ACKNOWLEDGMENTS

The authors thank Biuse Casaponsa, Simona Donzelli, Michele Liguori, Domenico Marinucci, Sabino Matarrese and Patricio Vielva for useful comments. The authors acknowledge partial financial support from the Spanish Ministerio de Economía y Competitividad project AYA2010-21766-C03-01 and the Consolider Ingenio-2010 Programme project CSD2010-00064. The authors acknowledge the computer resources, technical expertise and assistance provided by the Spanish Supercomputing Network (RES) node at Universidad de Cantabria. We also acknowledge the use of LAMBDA, support for which is provided by the NASA Office of Space Science. The work has also used the software package HEALPix (Górski et al. 2005). We acknowledge the use of the pre-launch Planck Sky Model simulation package (Delabrouille et al. 2012).
